GRADE 100%

Recurrent Neural Networks

LATEST SUBMISSION GRADE

100%

 Suppose your training examples are sentences (sequences of words). Which of the following refers to the jth word in the 1/1 point i^{th} training example?

- $\bigcirc \ x^{< i > (j)}$
- $\bigcirc \ x^{(j) < i>}$
- $\bigcirc \ x^{< j > (i)}$

We index into the i^{th} row first to get the i^{th} training example (represented by parentheses), then the j^{th} column to get the j^{th} word (represented by the brackets).

2. Consider this RNN:

1/1 point

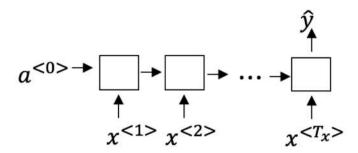

This specific type of architecture is appropriate when:

- \bigcirc $T_x = T_y$
- $\bigcap T_x < T_y$
- $\bigcap T_x > T_y$
- $\bigcap T_x = 1$

It is appropriate when every input should be matched to an output.

3. To which of these tasks would you apply a many-to-one RNN architecture? (Check all that apply).

1/1 point

- Speech recognition (input an audio clip and output a transcript)
- Sentiment classification (input a piece of text and output a 0/1 to denote positive or negative sentiment)

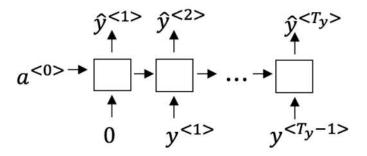

✓ Correct

- ☐ Image classification (input an image and output a label)
- Gender recognition This document is available on

4. You are training this RNN language model.

1/1 point

At the t^{th} time step, what is the RNN doing? Choose the best answer.

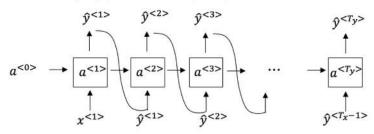

- $\bigcirc \ \, \mathsf{Estimating}\,P\big(y^{<1>},y^{<2>},\dots,y^{< t-1>}\big)$
- \bigcirc Estimating $P(y^{< t>})$
- $\bigcirc \ \ \mathsf{Estimating} \ P\big(y^{< t>} \mid y^{<1>}, y^{<2>}, \ldots, y^{< t>}\big)$

Yes, in a language model we try to predict the next step based on the knowledge of all prior steps.

5. You have finished training a language model RNN and are using it to sample random sentences, as follows:

1/1 point

What are you doing at each time step t?

- \bigcirc (i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as $\hat{y}^{< t>}$. (ii) Then pass the ground-truth word from the training set to the next time-step.
- \bigcirc (i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as $\hat{y}^{< t>}$, (ii) Then pass the ground-truth word from the training set to the next time-step.
- \bigcirc (i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as $\hat{y}^{< t>}$. (ii) Then pass this selected word to the next time-step.
- (i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as $\hat{y}^{< t>}$, (ii) Then pass this selected word to the next time-step.

✓ Correct Yes!

6. You are training an RNN, and find that your weights and activations are all taking on the value of NaN ("Not a Number"). Which of these is the most likely cause of this problem?

- Vanishing gradient problem.
- Exploding gradient problem,
- \bigcirc ReLU activation function g(.) used to compute g(z), where z is too large.
- Sigmoid activation function g(.) used to compute g(z), where z is too large.

✓ Correct

7. Suppose you are training a LSTM. You have a 10000 word vocabulary, and are using an LSTM with 100-dimensional activations $a^{< t>}$. What is the dimension of Γ_u at each time step?

- 01
- 100
- 300
- 0 10000

8. Here're the update equations for the GRU.

GRU

$$\begin{split} \tilde{c}^{< t>} &= \tanh(W_c [\Gamma_r * c^{< t-1>}, x^{< t>}] + b_c) \\ \Gamma_u &= \sigma(W_u [c^{< t-1>}, x^{< t>}] + b_u) \\ \Gamma_r &= \sigma(W_r [c^{< t-1>}, x^{< t>}] + b_r) \\ c^{< t>} &= \Gamma_u * \tilde{c}^{< t>} + (1 - \Gamma_u) * c^{< t-1>} \end{split}$$

 $a^{< t>} = c^{< t>}$

Alice proposes to simplify the GRU by always removing the Γ_n . I.e., setting Γ_n = 1. Betty proposes to simplify the GRU by removing the Γ_r . I. e., setting Γ_r = 1 always. Which of these models is more likely to work without vanishing gradient problems even when trained on very long input sequences?

- \bigcirc Alice's model (removing Γ_u), because if $\Gamma_r \approx 0$ for a timestep, the gradient can propagate back through that timestep without much decay.
- \bigcirc Alice's model (removing Γ_u), because if $\Gamma_r \approx 1$ for a timestep, the gradient can propagate back through that
- igotimes Betty's model (removing Γ_r), because if $\Gamma_upprox 0$ for a timestep, the gradient can propagate back through that timestep without much decay.
- \bigcirc Betty's model (removing Γ_r), because if $\Gamma_u \approx 1$ for a timestep, the gradient can propagate back through that timestep without much decay.

✓ Correct

Yes. For the signal to backpropagate without vanishing, we need $e^{< t>}$ to be highly dependant on $e^{< t-1>}$.

9. Here are the equations for the GRU and the LSTM:

1/1 point

1/1 point

GRU

 $c^{< t>} = \Gamma_u * \tilde{c}^{< t>} + \Gamma_f * c^{< t-1>}$

LSTM

 $a^{< t>} = \Gamma_o * c^{< t>}$

From these, we can see that the Update Gate and Forget Gate in the LSTM play a role similar to _____ and ____ in the GRU. What should go in the the blanks?

- $\bigcap \Gamma_u$ and Γ_r
- $\bigcirc \ 1 \Gamma_w \text{ and } \Gamma_u$
- $\bigcirc \ \ \Gamma_r \ \text{and} \ \Gamma_u$

✓ Correct

Yes!

Yes, correct!

10. You have a pet dog whose mood is heavily dependent on the current and past few days' weather. You've collected data for the past 365 days on the weather, which you represent as a sequence as $x^{<1>}, \dots, x^{<365>}$. You've also collected data on your dog's mood, which you represent as $y^{<1>}, \dots, y^{<365>}$. You'd like to build a model to map from $x \to y$. Should you use a Unidirectional RNN or Bidirectional RNN for this problem? Bidirectional RNN, because this allows the prediction of mood on day t to take into account more information. Bidirectional RNN, because this allows backpropagation to compute more accurate gradients. $\textbf{ Our Unidirectional RNN, because the value of } y^{<1>} \text{ depends only on } x^{<1>}, \dots, x^{<1>}, \text{ but not on } x^{<1+1>}, \dots, x^{<305>} \text{ or } x^{<1} \text{ and } x^{<1} \text{ or } x^{<$ \bigcirc Unidirectional RNN, because the value of $y^{< t>}$ depends only on $x^{< t>}$, and not other days' weather. ✓ Correct
